## Pocket V2N Protocol

An adaption of the Rain Tree Gossip Protocol for the Pocket Network Consensus Module

## Rain Tree Gossip is:

- Binary Tree distribution with 3 branches*
- ACK/Adjust/Resend at top level to insure against loss of trunk or major branches.
- Optional redundancy layer to insure against nonparticipation and incomplete lists without the ACK/Resend overhead.
- Double Dasisy Chain clean-up layer to insure 100\% message propagation in all cases.
* For clarity of presentation, the discussion and diagrams in the first part of this document all reflect 2 branch trees. Three branch begins at slide 13.

## Binary Tree...

- For any set of sorted, randomly distributed data, Binary Tree is the fastest possible lookup method.
- Rain Tree requires that all participant nodes have a sorted list (partial or complete), of target nodes.

## ACK/Adjust/Resend

- Rain Tree messages are sent with logical level numbers.
- Origin level number is determined by the message source node. ( = highest position bit in size of list)
- Level number is decremented by one when passed down.

4 Layer Network
4 ACKs being passed back To layer 4 sender from layer 3 recipient

4

## ACK/Adjust/Resend (pg 2)

- Failure to receive an ACK within time-out causes sender to select next 2 nodes ( $+1 \&-1$ ) in list and resend with decremented level number.
- Due to the "tricky" nature of time-outs, Adjust/Resend only happens once per target. Replacement nodes do not ACK.

## Department of Redundancy Department

- IF... Every node had the exact same list AND...
- IF... Every node was $100 \%$ reliable AND...
- IF... 100\% of communications were successful
- THEN... Redundancy would not be desirable.

## Meanwhile... in the real world..

- Communications fail! Networks don't actually work the way that simulations often assume they will.

## A short pause to reorganize the drawing (smoke 'em if you got 'em)

- We will flatten the drawing to make it look more like a list. Because that's what it really is. Then redraw it to show the same information in a more useful format

## Now then... Let's get redundant.. again

- This sample shows one additional redundancy layer of 1 comm per node.
- Initial distribution required: 14 comms + 2 acks and took 3 ticks to complete.
- Redundancy layer required 15 comms and took 1 tick.

## Dasie Chain Clean-up \& list maintenance layer.

- When a message reaches layer one, the receiving node sends a layer zero IGYW (I got. You want?) message to its right hand and left hand peers.
- When a node receives an IGYW, it checks the message hash vs. its recently received messages and responds with a yes/no message.
- Latency and/or lack of response are applied to peer and list management if appropriate for the application. If the answer is: "Yes. I want it", the message is passed on.
- This Bi-Directional Dasiy Chain counts as two additional redundancy layers and insures eventual 100\% delivery to all functional nodes.

## Let's Review: Rain Tree is...

- Binary Tree distribution with 3 branches*
- ACK/Adjust/Resend at top level to insure against loss of trunk or major branches.
- Optional redundancy layer to insure against nonparticipation and incomplete lists without the ACK/Resend overhead.
- Dasiy Chain clean-up layer to insure 100\% message propogation in all cases.
* For clarity of presentation, the discussion and diagrams in the first part of this document all reflect 2 branch trees. Three branch reasoning is discussed next.

## The Third Man. Structural Redundancy durring distribution

- A close look at our binary chart reveals an interesting fact.
- The Green Node (message originator) is divorced from the distribution process as soon as his two messages have been sent and ACKed.
- But, what if we leverage the fact that he is by definition:
- Available, informed, capable and cooperative?

## The Third Man. Continued

- After completing his duties at level 4 , he demotes himself to level 3 acts as he should, then self-demotes again to level 2, etc, etc.

This drawing shows the concept of demote and

- In fact, all nodes follow this self-demoting behavior.

## Side Note: Unneeded rules in V2N

- In networks with highly variant sizes of peer lists Rain Tree has two cases of behavior modification which serve to mitigate the effects of a message source node miscalculating the network size and launching messages with an insufficient or excessive level number. Namely, increment/non-decrement and MaxLevelAdjustment.
- Nodes on Pocket V2N have access to the blockchain source of truth, so these mitigators are not needed in this application.

## Why we ACK and adjust on the first layer but nowhere else

Rain Tree splits the target universe into 3 overlapping sets, such that each of the first 3 participants (1, 10 and 19 in the diagram below) is responsible for $2 / 3 \mathrm{rds}$ of the remaining nodes.

Although we would still have full coverage with the loss of any one zone..
We would not have the full structural redundancy factor of 2 within that subsection.
The clean-up layer and any included redundancy layer would (of course) take care of potential issues.

## Ready for some real fun?

## Real Rain Tree levels are multiples of $3 .$. $27=$ max size of 4 layer network.

Let's work through 3 layers of a 4 layer network. Can you think of anything more fun?

## Scaling it up.

- The 4 layer, 27 node network that we have just drawn has the following characteristics:
- Layer 4: Anodes $=1$, Comms $=2$, ACKs $=2$, Ticks $=3$
- Layer 3: Anodes $=3$, Comms $=6$, ACKs $=0$, Ticks $=2$
- Layer 2: Anodes = 9, Comms = 18, ACKs =0, Ticks = 2
- Redundacy layer 1: Anodes = 27, Comms =27, ACKS =0, Ticks =1
- Clean-up Layer 0: Anodes = 27, IGYWs = 54, ACKS = 54, Ticks $=3$
- TOTAL(n=27): Comms+IGUWs = 107, ACKs = 61, Ticks = 11
- Redundancy: (Comms+IGUWs) / nodes $=\underline{\underline{3.96}}$
- TOTAL(n=9): Comms+IGUWs = 53, ACKs = 25, Ticks $=10$
- Redundancy: $($ Comms+IGUWs) $/$ nodes $=\underline{\underline{5.88}}$

## From perfect to worst case

$3 \times 3 \times 3=27$ Best Case
Largest prime number in range $=23$, Worst Case

 15 | 16 | 17 | 18 | 19 | 20 | 21 | 22 | 23 | 1 | 2 | 4 | 4 | 4 | 5 | 4 | 6 | 7 | 8 | 9 | 10 |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- |

## Fire Away!!

- Let's knock down 8 of these bad boys. $=35 \%$

Notice: We're knocking down a key player and not even applying the ACK/adjust
1516171819221222312345567891011121314
151617181920 21 222312 3 345 6) $789(1011121314$

15 of 23 nodes on line.
12 of them got the message. (3 got it twice)
Clean up layer fixes it all in 2 ticks.

## Simple Math makes life easy.

- How do you determine the nuber of layers in the network?
- topLayer = count factors of 3 then add 1
- ===============================================
- How to determine targetListSize at spesfic layer?
- targetListSize $=$ (topLayer - currentLayer) $\times 0.666 \times$ fullListSize
- ===============================================
- How do nodes determine which 2 nodes to send to?
- Target 1 = Node postion + targetListSize/3 (roll over if needed)
- Target $2=$ Node position + targetListSize/1.5 (roll over if needed)

## This will scale.

Tripple the nodes... Ticks $=+2$

| Nodes | Comms | ACKs | Ticks |
| ---: | ---: | ---: | ---: |
| 27 | 107 | 56 | 11 |
| 81 | 323 | 164 | 13 |
| 243 | 971 | 488 | 15 |
| 729 | 2,915 | 1,460 | 17 |
| 2,187 | 8,747 | 4,376 | 19 |
| 6,561 | 26,243 | 13,124 | 21 |
| 19,683 | 78,731 | 39,368 | 23 |
| 17,049 | 236,195 | 118,100 | 25 |
